[dwharder@gmail.com](mailto:dwharder@gmail.com)

# Introduction

- In this topic, we will
  - Give a description of systems of 1<sup>st</sup>-order initial-value problems (IVPs)
  - Discuss their solutions, if they can be found
  - Describe how operations translate to vector-space operations of vector addition and scalar multiplication
  - Look at converting our 1<sup>st</sup>-order solvers to solving systems of 1<sup>st</sup>-order IVPs
  - Go over some examples

# Systems of initial-value problems

- Suppose we have a system of two 1<sup>st</sup>-order IVPs

$$y^{(1)}(t) = -y(t) - 2z(t) \quad y(0) = 1$$

$$z^{(1)}(t) = -z(t) + 2y(t) \quad z(0) = 2$$

- This has a unique solution:

$$y(t) = e^{-t} (\cos(2t) - 2 \sin(2t))$$

$$z(t) = e^{-t} (2 \cos(2t) + \sin(2t))$$

- Problem: this system has no known solution:

$$y^{(1)}(t) = -ty(t) - 2z(t) \quad y(0) = 1$$

$$z^{(1)}(t) = -z(t) + 2y(t) \quad z(0) = 2$$

# Systems of initial-value problems

- Here is another such problem:

$$x^{(1)}(t) = 0.02x(t) - 0.1x(t)y(t) \quad x(0) = 5233$$

$$y^{(1)}(t) = -0.04y(t) + 0.02x(t)y(t) \quad y(0) = 323$$

# Systems of initial-value problems

- Here is another problem that began a revolution in mathematics:

$$x^{(1)}(t) = 10(y(t) - x(t)) \quad x(0) = 1$$

$$y^{(1)}(t) = x(t)(28 - z(t)) - y(t) \quad y(0) = 1$$

$$z^{(1)}(t) = x(t)y(t) - \frac{8}{3}z(t) \quad z(0) = 1$$

- This is a simplified model of fluid convection, including:
  - The rate of convective motion
  - The temperature difference between rising and falling fluid parcels
  - The deviation of the temperature profile from a linear state

# The Lorenz equations

- This second equation is responsible for the term *the butterfly effect*

Dan Quinn via Wikipedia

# Vector-valued functions of a real variable

- We would like to approximate solutions to such systems
  - What approach do we use?
- Let's create a vector-valued function:

$$\mathbf{u}(t) = \begin{pmatrix} x(t) \\ y(t) \\ z(t) \end{pmatrix} = \begin{pmatrix} u_1(t) \\ u_2(t) \\ u_3(t) \end{pmatrix}$$

- The derivative is as follows:

$$\mathbf{u}^{(1)}(t) = \begin{pmatrix} x^{(1)}(t) \\ y^{(1)}(t) \\ z^{(1)}(t) \end{pmatrix} = \begin{pmatrix} u_1^{(1)}(t) \\ u_2^{(1)}(t) \\ u_3^{(1)}(t) \end{pmatrix}$$

# Vector-valued functions of a real variable

- We can define such a function:

$$\mathbf{u}(t) = \begin{pmatrix} t + \sin(t) \\ \cos(t) - 1 \\ t \sin(t) \end{pmatrix}$$

- In this case, we have

$$\mathbf{u}^{(1)}(t) = \begin{pmatrix} 1 + \cos(t) \\ -\sin(t) \\ \sin(t) + t \cos(t) \end{pmatrix}$$

# Vector-valued functions of a real variable

- A 3-dimensional vector-valued function of a real variable could represent:
  - The  $x$ ,  $y$  and  $z$  coordinates of a drone at time  $t$
  - The voltages at three nodes in a circuit at time  $t$
  - The temperature readings from three sensors at time  $t$
- You could have fifty sensors, resulting in a 50-dimensional vector-valued function of a real variable
- In each case, the derivative gives you the instantaneous rate-of-change of that vector-valued function
  - E.g., how fast the drone is moving north, west and vertically up

# Vector-valued functions of a real variable

- For example, you may have a drone flying in a figure eight over an area:

$$\mathbf{u}(t) = \begin{pmatrix} 10 \sin(t) \\ 10 \cos(3t) \\ 100 \end{pmatrix}$$

- The direction of travel is given by:

$$\mathbf{u}^{(1)}(t) = \begin{pmatrix} 10 \cos(t) \\ -30 \sin(3t) \\ 0 \end{pmatrix}$$

- The speed is given by

$$\|\mathbf{u}^{(1)}(t)\|_2 = \sqrt{100 \cos^2(t) + 900 \sin^2(3t)}$$

- The speed varies between 5 m/s and 31 m/s

# Approximating movement

- Notice that if we have a position vector  $\mathbf{u}$  and velocity vector  $\mathbf{v}$ ,
  - Then assuming the velocity is constant,  
we can estimate the position one time step into the future

$$\mathbf{u} + h\mathbf{v}$$

# Systems of 1<sup>st</sup>-order initial-value problems

- Now, can't we do the same with differential equations?

$$x^{(1)}(t) = 0.02x(t) - 0.1x(t)y(t) \quad x(0) = 5233$$

$$y^{(1)}(t) = -0.04y(t) + 0.02x(t)y(t) \quad y(0) = 323$$

$$\mathbf{u}(t) = \begin{pmatrix} u_1(t) \\ u_2(t) \end{pmatrix} \quad \mathbf{u}^{(1)}(t) = \begin{pmatrix} u_1^{(1)}(t) \\ u_2^{(1)}(t) \end{pmatrix}$$

$$\mathbf{u}^{(1)}(t) = \begin{pmatrix} 0.02u_1(t) - 0.1u_1(t)u_2(t) \\ -0.04u_2(t) + 0.02u_1(t)u_2(t) \end{pmatrix} \quad \mathbf{u}(t_0) = \mathbf{u}_0 = \begin{pmatrix} u_1(t_0) \\ u_2(t_0) \end{pmatrix} = \begin{pmatrix} 5233 \\ 323 \end{pmatrix}$$

$$= \mathbf{f}(t, \mathbf{u})$$

# Systems of 1<sup>st</sup>-order initial-value problems

- Now, can't we do the same with differential equations?

$$y^{(1)}(t) = -ty(t) - 2z(t) \quad y(0) = 1$$

$$z^{(1)}(t) = -z(t) + 2y(t) \quad z(0) = 2$$

$$\mathbf{u}^{(1)}(t) = \begin{pmatrix} -tu_1(t) - 2u_2(t) \\ -u_2(t) + 2u_1(t) \end{pmatrix} \quad \mathbf{u}(0) = \begin{pmatrix} 1 \\ 2 \end{pmatrix}$$
$$= \mathbf{f}(t, \mathbf{u})$$

# Systems of 1<sup>st</sup>-order initial-value problems

- Similarly, this system of three initial-value problems can be

$$x^{(1)}(t) = 10(y(t) - x(t)) \quad x(0) = 1$$

$$y^{(1)}(t) = x(t)(28 - z(t)) - y(t) \quad y(0) = 1$$

$$z^{(1)}(t) = x(t)y(t) - \frac{8}{3}z(t) \quad z(0) = 1$$

$$\mathbf{u}(t) = \begin{pmatrix} u_1(t) \\ u_2(t) \\ u_3(t) \end{pmatrix} \quad \mathbf{u}^{(1)}(t) = \begin{pmatrix} u_1^{(1)}(t) \\ u_2^{(1)}(t) \\ u_3^{(1)}(t) \end{pmatrix}$$

$$\mathbf{u}^{(1)}(t) = \begin{pmatrix} 10(u_2(t) - u_1(t)) \\ u_1(t)(28 - u_3(t)) - u_2(t) \\ u_1(t)u_2(t) - \frac{8}{3}u_3(t) \end{pmatrix} = \mathbf{f}(t, \mathbf{u}) \quad \mathbf{u}(0) = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}$$

# Euler's method

- Let's see how this works with Euler's method:

$$\mathbf{u}^{(1)}(t) = \mathbf{f}(t, \mathbf{u}(t))$$

$$\mathbf{u}(t_0) = \mathbf{u}_0$$

$$\mathbf{u}(t_0 + h) \approx \mathbf{u}_0 + h\mathbf{f}(t_0, \mathbf{u}_0)$$

- Thus, we use  $\mathbf{u}_{k+1} \leftarrow \mathbf{u}_k + h\mathbf{f}(t_k, \mathbf{u}_k)$

# Heun's method

- Let's see how this works with Heun's method:

$$\mathbf{u}^{(1)}(t) = \mathbf{f}(t, \mathbf{u}(t))$$

$$\mathbf{u}(t_0) = \mathbf{u}_0$$

$$\mathbf{s}_0 \leftarrow \mathbf{f}(t_k, \mathbf{u}_k)$$

$$\mathbf{s}_1 \leftarrow \mathbf{f}(t_k + h, \mathbf{u}_k + h\mathbf{s}_0)$$

$$\mathbf{u}_{k+1} \leftarrow \mathbf{u}_k + h \frac{\mathbf{s}_0 + \mathbf{s}_1}{2}$$

# 4<sup>th</sup>-order Runge-Kutta method

- Let's see how this works with the 4<sup>th</sup>-order Runge-Kutta method:

$$\mathbf{u}'(t) = \mathbf{f}(t, \mathbf{u}(t))$$

$$\mathbf{u}(t_0) = \mathbf{u}_0$$

$$\mathbf{s}_0 \leftarrow \mathbf{f}(t_k, \mathbf{u}_k)$$

$$\mathbf{s}_1 \leftarrow \mathbf{f}\left(t_k + \frac{1}{2}h, \mathbf{u}_k + \frac{1}{2}h\mathbf{s}_0\right)$$

$$\mathbf{s}_2 \leftarrow \mathbf{f}\left(t_k + \frac{1}{2}h, \mathbf{u}_k + \frac{1}{2}h\mathbf{s}_1\right)$$

$$\mathbf{s}_3 \leftarrow \mathbf{f}(t_k + h, \mathbf{u}_k + h\mathbf{s}_2)$$

$$\mathbf{u}_{k+1} \leftarrow \mathbf{u}_k + h \frac{\mathbf{s}_0 + 2\mathbf{s}_1 + 2\mathbf{s}_2 + \mathbf{s}_3}{6}$$

# Implementation

- Recall our implementation of Euler's method:

```
std::tuple<double *, double *, double *>
euler( double f( double t, double y ),
      std::pair<double, double> t_rng, double y0, unsigned int n ) {
    double h{ (t_rng.second - t_rng.first)/n };

    double *ts{ new double[n + 1] };
    double *ys{ new double[n + 1] };
    double *dys{ new double[n + 1] };

    ts[0] = t_rng.first;
    ys[0] = y0;
    dys[0] = f( ts[0], ys[0] );

    for ( unsigned int k{0}; k < n; ++k ) {
        ts[k + 1] = ts[0] + h*(k + 1);
        ys[k + 1] = ys[k] + h*dys[k];
        dys[k + 1] = f( ts[k + 1], ys[k + 1] );
    }

    return std::make_tuple( ts, ys, dys );
}
```

# Implementation

- Let's update it for vector-valued functions:

```
template <unsigned int N>
std::tuple<double *, vec<N> *, vec<N> *>
euler( vec<N> f( double t, vec<N> y ),
       std::pair<double, double> t_rng, vec<N> y0, unsigned int n ) {
    double h{ (t_rng.second - t_rng.first)/n };

    double *ts{ new double[n + 1] };
    vec<N> *ys{ new vec<N>[n + 1] };
    vec<N> *dys{ new vec<N>[n + 1] };

    ts[0] = t_rng.first;
    ys[0] = y0;
    dys[0] = f( ts[0], ys[0] );

    for ( unsigned int k{0}; k < n; ++k ) {
        ts[k + 1] = ts[0] + h*(k + 1);
        ys[k + 1] = ys[k] + h*dys[k];
        dys[k + 1] = f( ts[k + 1], ys[k + 1] );
    }

    return std::make_tuple( ts, ys, dys );
}
```

# Implementation

- All of this worked because for our vector class:
  - We defined all possible arithmetic operators on pairs of vectors
  - We also defined all possible arithmetic operators for scalar multiplication
- We can make similar changes to the adaptive algorithms:
  - Only one additional trivial change is required for the adaptive algorithms:
    - We must compare two vectors with the norm:

```
double a{ eps_abs*h/(2.0*norm( y - z )) };  
double a{ std::pow( eps_abs*h/(2.0*norm( y - z )), 0.25 ) };
```

# Implementation

- Recall our problem and solution:

$$y^{(1)}(t) = -y(t) - 2z(t) \quad y(0) = 1$$

$$z^{(1)}(t) = -z(t) + 2y(t) \quad z(0) = 2$$

$$y(t) = e^{-t} (\cos(2t) - 2 \sin(2t))$$

$$z(t) = e^{-t} (2 \cos(2t) + \sin(2t))$$

# Implementation

- The greatest issue is writing down the functions

$$y^{(1)}(t) = -ty(t) - 2z(t) \quad y(0) = 1$$

$$z^{(1)}(t) = -z(t) + 2y(t) \quad z(0) = 2$$

```
vec<2> f( double t, vec<2> u ) {  
    return vec<2>{ -t*u[0] - 2.0*u[1],  
                  -u[1] + 2.0*u[0] };  
}
```

```
vec<2>{ 1.0, 2.0 }
```

# Implementation

- Recall that this last problem did not have a closed-form solution, however, we can still approximate it

$$y^{(1)}(t) = -ty(t) - 2z(t) \quad y(0) = 1$$

$$z^{(1)}(t) = -z(t) + 2y(t) \quad z(0) = 2$$

# Implementation

- The greatest issue is writing down the functions

$$x^{(1)}(t) = 10(y(t) - x(t)) \quad x(0) = 1$$

$$y^{(1)}(t) = x(t)(28 - z(t)) - y(t) \quad y(0) = 1$$

$$z^{(1)}(t) = x(t)y(t) - \frac{8}{3}z(t) \quad z(0) = 1$$

```
vec<3> f( double t, vec<3> u ) {  
    return vec<3>{ 10.0*(u(1) - u(0)),  
                  u(0)*(28.0 - u(2)) - u(1),  
                  u(0)*u(1) - 8.0/3.0*u(2) };  
}
```

```
vec<3>{ 1.0, 1.0, 1.0 }
```

# Implementation

- Let's go the opposite direction:

```
vec<3> f( double t, vec<3> u ) {  
    return vec<3>{ -u(0) - u(1)*u(2) + t*t,  
                  -u(1)*u(2) + 2.5*t,  
                  -u(2) - u(0) + sin(t) };  
}
```

$$x^{(1)}(t) = -x(t) - y(t)z(t) + t^2$$

$$y^{(1)}(t) = -y(t)z(t) + 2.5t$$

$$z^{(1)}(t) = -z(t) - x(t) + \sin(t)$$

# Summary

- Following this topic, you now
  - Have a deeper appreciation for systems of initial-value problems
  - Understand a system of initial-value problems can be converted to vector form
  - Know that this requires essentially no changes to the solvers
    - All of the arithmetic seamlessly translates to vector addition or scalar multiplication
  - Have an idea how to formulate such problems
